

ShopSphere Rollback Plan

Detecting a Failed Release

A failed production release is detected through the **monitoring configured in Task 1**. When that monitoring reports that the production application is unavailable, unhealthy, or behaving incorrectly after a deployment, the release is treated as failed and rollback begins.

Rollback Procedure

1. Confirm that the problem started after the latest production deployment and identify the failed deployment in Vercel.
2. Open the **Vercel deployment history** for the affected ShopSphere project.
3. Identify the most recent deployment that was known to be working before the failed release.
4. Promote/redeploy that previous working deployment as the current **Production** deployment.
5. Verify the production frontend and backend are responding normally.
6. Recheck the **Task 1 monitoring** to confirm that the system has returned to a healthy state.
7. Keep the failed release available for investigation rather than deleting it immediately, and fix the cause before attempting another production deployment.
